2 Dictionary

- Fragment: An graphical element independent from any other element.
- Adapter: A class designed to adapt the interface of one class with the interface of another.
- Thread: a process that runs within the application. Takes messages from the current program execution and acts upon it.

3 Descriptions of classes

3.1 MainActivity

This class should just be a joiner class for all the fragments.

3.1.1 setOriginalImage

This should only be called by the ImageDisplayFragment when the source image changes.

It changes the reference to the `m_origImage` value to be a reference to the image in the `ImageDisplayFragment` so that it can be easily be passed on to be halftoned.

3.1.2 setHalftonedImage

This should call the `setHalftonedImage()` method in the `ImageDisplayFragment` class so that a resultant halftoned image can be displayed to the user.

3.2 ImageDisplayAdapter

This is supposed to showcase the original image as well as the halftoned image, swapping to the halftoned image when it updates.

3.2.1 setHalftonedImage

Sets the halftoned image to the passed in variable. Should also bring the image to the forefront so that the user can see the results.

3.2.2 setOriginalImage

Callback for when the user selects an new image source. This sets the `m_origImage` reference in the `MainActivity` so that it can be passed onto the `HalftoneInterfaceAdapter` when the user decides to apply settings.

3.3 OriginalImageDisplayFragment

This fragment should show the user images before and after halftoning.

Should also be able to select images from file and camera. Maybe those buttons should be in the actionbar instead, so that they are visible all the time. Not a big issue right now though.

Right now it does not matter how it is done, but something nice should be made so that swapping back to the original image should be painless and automatic when settings are changed.

Interfacing is done via a callback to the host class that implements a method to set the source image globally.

3.4 HalftonedImageDisplayFragment

Shows the user the resultant image from the halftoning once it is done. Otherwise, the user should not be able to swap to this fragment if the image

has not been processed yet. Also, buttons for sharing/saving the image are only displayed when the image has been processed.

3.4.1 setImage

Sets the displayed image (as well as the image for sharing/saving) to the passed in bitmap.

3.5 HalftoneInterfaceAdapter

Note that this is an inner class of `MainActivity`.

This is what displays the settings for the current halftoning mode, mostly for encapsulation within the `MainActivity` so that no "special case" code has to be implemented in it.

Should implement a `ViewPager` so that the user can swipe between the halftoning modes that are implemented. Hopefully there will be more than one otherwise this will be wasted.

Each element in the `ViewPager` should be a fragment that implements its own interface to the user.

3.5.1 setImage

Sets the reference image to be passed on to the halftone implementation when the user presses "Apply"

3.6 Halftone

This is an interface that all halftoning methods should implement. Basic stuff.

3.6.1 setImage

Sets the source image that the halftoning should be applied to once the user presses apply.

3.7 BasicHalftone

This is the meat of the app, applies the halftoning that we all know and love(?).

Should be able to set the grid size, there really shouldn't be much more than that in this implementation.

Side note:

3.7.1 Proposal:

Halftoning usually takes a long time (>10s for large images.) A solution should be made for this.

- multiple threads could be used to work around the slowness of the application.
 - This would give the advantage of not slowing down the GUI
 - However, it would be harder to code. Maybe another spike is in order for implementation?
- A hard limit on the grid size would also be sufficient
 - "worse" than the threaded way because the application would appear to freeze when being halftoned. This is VERY bad.
 - Worse output due to each dot being bigger than any other way.
 - Not using the full power of the processor (We need all we can get)

3.8 AdvancedHalftone

This is currently just a placeholder in case we extend the application to do more than basic halftoning.

Implementations:

- Different colors
- Different angles
- Adding text
- Background colors
- Sepia
- dithering
